ORGiD Protocol Upgrade

ORGiD is a global decentralized business registry that streamlines the burdensome process of verifying identities between business entities.

It's similar to government-maintained registries except that ORGiD has no central authority, as it's completely decentralized and governed by its users. By connecting

organizations directly to each other, ORGiD eliminates both the bureaucracy and the hassle of navigating dozens of different business registries worldwide, each with different standards, languages, and trustworthiness.

ORGiD protocol is the SSI system that enables participation in the Winding Tree Decentralized Travel Marketplace. Read more about ORGiD [here](#).

. . .

The ORGiD protocol is going to be upgraded in Q1 2022.

Here is an overview of the goals for this update and the details of the changes.

First, let's look at the main goals of why an update is needed.

Objectives of the changes

Lower
usage costs

More
flexibility

Additional
dev tools

Better UI
and UX

Supporting
more
use cases

Change and new features

1. ORGiD smart contract is now an NFT

The new ORGiD smart contract is now fully compatible with the [ERC-721](#) standard of non-fungible tokens. So, every ORGiD is now an NFT. That means that from now it is possible to hold an organization and manage ownership using any wallet supporting NFTs. It is now very easy to transfer an organisation to someone else, as you just send it as a regular token.

Eventually, it will be possible to trade your ORGiD on NFT marketplaces. It is a very useful change as it increases the interoperability of ORGiD. It's accompanied by some other key functionalities such as not needing to send on-chain transactions to make profile changes, and an interface to manage the ORGiD delegates.

2. Organization profile management flow

Here are the changes to an organization profile management flow.

3. ORGiD DID format

The ORGiD protocol now uses a new DID format that supports multi-chain ORGiD usage.

The new smart contract will be deployed in multiple networks and users will be able to choose which blockchain network is more suitable for them. It has also already been deployed in some test networks. All these deployments are verified except for Sokol.

That means that it is already possible to interact with the contract using the Etherscan Dapp interface for testing.

The ORGiD protocol now lives in the multi-chain environment and the new DID format is extended with a chain identifier which allows you to know in

which blockchain it has been issued.

For example, looking at the DID below we can see it belongs to the xDAI network (100 is the Id of xDAI). You can look up all chain IDs at [Chainlist](#).

4. ORG.JSON Schema

The ORG.JSON package now provides four separate schemas that can be used for object validation.

These are (i) ORG.JSON schema, (ii) ORGiD Verifiable credential with NFT interface, (iii) Trust Assertion credential and (iv) NFT interface schema separately.

All the schemas are available in YAML and JSON schema formats.

Also, the package provides Typescript typings for every schema.

ORG.JSON schema received several additions.

Firstly, information about an organization hierarchy is moved from the smart contract to the metadata level. Now the ``legalEntity`` definition contains a set of links to ``organizationalUnits`` and vice versa, the ``organizationalUnit`` contains a link to ``parentOrganization``.

The ``verificationMethod`` definition is now extended with optional information about the method revocation. It is recommended that once added the verification method should never be removed from the

organization profile. In case of the method compromising or planned revocation, this method should be marked as revoked.

The ``capabilityDelegation`` is the new definition that should contain a list of verification methods that can be used for an ORGiD Verifiable credential verification instead of the default method.

Type of ``trustAssertions`` records is changed. Now, these records are not raw assertions claims but special Trust Assertion verifiable credentials that contain a signed result of assertion validation.

5. ORGiD SDK

And the biggest update. Now the ORGiD protocol has its Software Development Kit with documentation. The ORGiD SDK contains a set of utilities and libraries that help developers to create applications that use the protocol features and extend them.

All these tools are well covered with tests and have documentation that is hosted using Github pages. The current version of the SDK is stable but is still in beta.

More information about these packages can be found on the [documentation site](#).

The ``org.id-auth`` package contains libraries for working with authentication tokens, verifiable credentials and cryptographic keys. Using these libraries you can generate and convert keys in different formats, create and verify tokens and credentials.

The ``org.id-core`` library is dedicated to being used for interaction with the ORGiD smart contract.

The ORGiD command-line utility is able to manage the organization profiles.

For this moment this is the only feature but this utility will be extended with more features soon.

And the last package to mention is the ORGiD DID resolver.

It is the programmatic utility for the resolution of the ORGiD identifiers that supports the new ORGiD flow and standards.

Next steps

If you'd like to see the full documentation of the upgrade go [here](#).

There are a lot of technical changes and innovations under the hood of the ORGiD SDK. The upcoming article will reveal new ideas and plans related to the general strategy of the ORGiD ecosystem development. We will talk about the decentralization and governance issues, about the new economic and tokenomics possibilities. **Stay tuned!**
